VII. Future Direction .....	14

## **I. Executive Summary**

In recent years, the state of California has succumbed an enormous amount of damage from greenhouse gases. These gases have created such a problem in the state of California that it has drawn attention towards new technologies such as electrical vehicles and solar power. All these new elements brought into society to keep away what is primarily harming our environment, the pollution. Thankfully, it's because of these new technologies that we are capable of tracking observed data to understand patterns and measurements such as Air Quality Index (AQI). Looking at pollution data allows us to better comprehend our atmosphere and regional environment. The data which was used to conduct this project was published through Kaggle. A user put together a dataset of collected quantitative data provided by the US Environmental Protection Agency (EPA).

For this project, I used multiple statistical methods to accurately predict major gas pollutants which influence pollution the most. My main idea for this project was to find which response variables are most significant in increasing a region's pollution.

I used many different models to predict such as Linear Regression, Ridge Regression, and Lasso. I also included a Best-Subset selection model to help classify the optimal number of variables to best predict the response variables. A PCR/PLS test was also conducted in this project, as well as a Regression Tree. Each of these models were compared to identify which tended the best accuracy with the lowest Root Mean Square Error (RMSE).

After using the methods that are mentioned above, it can be concluded that the Linear Regression model is the best model for the given dataset. From this, it's clear that each of the variables hold a relatable correlation with one another.

As far as future work for this project, I believe that it might be interesting to further investigate and understand deep learning models for this project. Furthermore, I believe adding more variables would be a bonus in the dataset and would lead to more clear models and better predictions.

## **II. Introduction**

In today's California society, many people are concerned with the recent inconsistency of the weather. California temperature has reached new all-time highs as well as lows. With the

pandemic already being a giant headache, this is an added dose especially for residents in California. Data is an important asset that is used as a tool and sense of guidance for making plans of action. As long as the topic of pollution is in discussion, we will continue to collect and use data to understand the proper steps that are needed to help protect and keep our environment clean and safe to breathe.

Regression is a statistical task which determines the strength and character of the relationship between some dependent  $y$  variable and a series of predictor variables. This form of analysis is key with the variables and numerical data given in the set. This will also play an important role as we try and identify patterns amongst each variable in the database.

### **III. The data**

The title of the dataset is “U.S Pollution Data” and the website that sourced the set is public and free, so no permission was needed permission to use this data.

The data includes a total of 22 variables, most of which was numeric including only few categorical. But this was not an issue during my pre-processing stages. The dataset is designed revolving around 4 major gas pollutants: Nitrogen Dioxide (NO<sub>2</sub>), Sulphur Dioxide (SO<sub>2</sub>), Carbon Monoxide (CO), and the Ozone (O<sub>3</sub>). The data collected was for every day in every County and State from the year 2000 to March 2021. There are a total of 1.4 million observations

### **IV. Data Cleansing + Preprocessing**

#### **1. Filter the Data**

The first thing that was needed to fix in the set was of course filtering out the states. The dataset incorporated every state in the United States, and we had to filter it in order to only display data in California. This required some use of Excel primarily because there were so many observations in the set and I would constantly find myself running into issues with RStudio not being able to load the data.

Next, I wanted to filter the set so that it shows me monthly observed data. The data given was for every single day so I managed to keep it uniform by making sure I only observed the first day of each month.

## 2. Remove Outliers

Finally, I removed any variables that were deemed to be insignificant in reaching my objective. These outliers include *address*, *city*, as well as others such as the *max/min first hour AQI/Mean* for the given chemical pollutant.

Successfully performing these actions led me to a new and more concise dataset of about 595,000 observations. Also being able to jump from 22 variables down to 6 variables. From here I was able to upload this data into RStudio, splitting the training and test data into the 80/20 ratio.

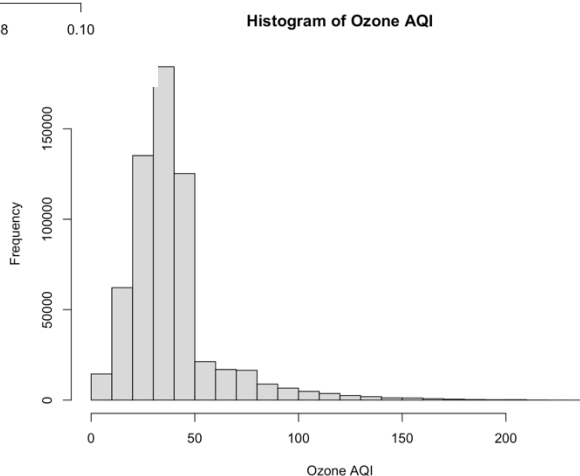

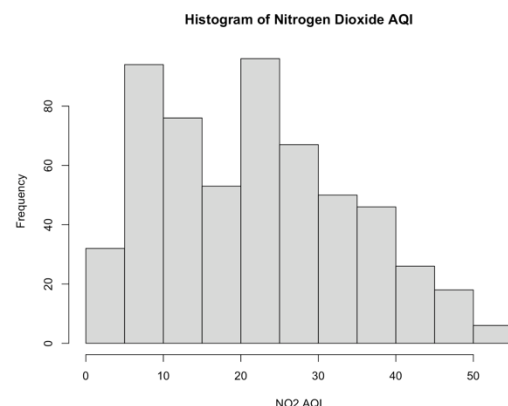

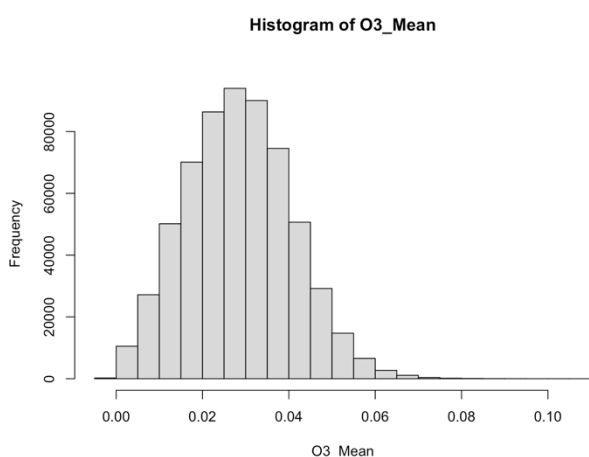

## 3. Data Summary + Visualization

Here is a summary of the cleansed data uploaded into R. You can see in the summary all the variables that were used in this project.

```
> summary(PData2)

Below includes some of the histograms for the numerical variables that were used in the regression analysis. Each variable is different as far as its distribution of value goes. This was unique to me as I grew more interest in wanting to explore for the best response and predictor variables.

## V. Model selection

Throughout each process, the objective remained consistent, which is to determine which model is best for accurately predicting for the Nitrogen Dioxide Air Quality Index, otherwise the NO2 AQI. According to the EPA, the same agency that collected the dataset, NO2 levels are classified as the most harmful gas pollutant to the atmosphere. It was because of this I chose this variable as the response.

### 1. Linear Regression Model

The objective of a linear regression model is to predict the value of an output variable (response) based on the value of an input (predictor) variables. The idea behind the model is to look at primarily whether a set of predictor variables do a good job in predicting a response variable? It also illustrates which specific variables are significant predictors to the response.

Linear Regression will be the first method used for the project because it is the simplest method and computes a clean easy to interpret model. The results from the model are shown below:

The first model includes all predictor variables, including the N02 mean for each observation.

```
lm(formula = N02_AQI ~ County + CO_AQI + CO_Mean + N02_AQI +  
  N02_Mean + S02_AQI + S02_Mean, data = PData2.train)
```

Residual standard error: 5.687 on 486818 degrees of freedom  
Multiple R-squared: 0.8485, Adjusted R-squared: 0.8484  
F-statistic: 1.947e+04 on 140 and 486818 DF, p-value: < 2.2e-16

From this model you can clearly see every County in California is factored in as predictor values. Something to note for AQI and in this model is that a negative coefficient indicates a decreased NO2 AQI value. Based on the measure of AQI a lower index is preferred over a higher index. A lower index illustrates a cleaner and more breathable atmosphere. For example, if you see from the model Kern County depicts a positive coefficient given the NO2 AQI as the response. This can be explained because Kern County is in none other than Bakersfield, CA. Bakersfield is known for its high air pollution given the area's high-emission industries. The climate conditions of the region also factor into play as it causes polluted air to become trapped in the valley. From this first model we can see that the R<sup>2</sup> value is very high at .85. Depicting that this model fits the data quite accurately. This is because the NO2 mean is included in this model. In my perspective, by allowing this to be a predictor variable, it leads to a higher R<sup>2</sup> value.

In the second model you will see that I removed the NO2 mean variable because I wanted to predict for the NO2 AQI without any biasness in the predictor variables. Below lies the results from the second model:

lm(Formula = NO2\_AQI ~ County + CO\_AQI + CO\_Mean + O3\_AQI + O3\_Mean +  
SO2\_AQI + SO2\_Mean, data = PData2.train)

Residual standard error: 8.771 on 486817 degrees of freedom  
Multiple R-squared: 0.6395, Adjusted R-squared: 0.6394  
F-statistic: 6125 on 141 and 486817 DF, p-value: < 2.2e-16

From this model you can see that the  $R^2$  value has decreased (.64), which is logically sensible as we are decreasing the number of variables and observations in our model. However, by removing the biased variable we can see our coefficients have also changed and we can see, especially as we look at each gas pollutant variable. In this model we can see other counties representing a positive coefficient. Los Angeles and San Bernardino County are all showing positive coefficients. This gives me indication that these counties produce high levels of NO2 AQI levels. This can be explained as Los Angeles is listed as the most polluted zip code in California. Where the County tends to the burning of fossil fuels, especially by vehicles, ships, planes and manufacturing, as well as its recent wildfires. San Bernardino is also highly polluted given its dry and hot climate.

Below includes the RMSE value from the second model (less than 1). It is clear that the model depiction is quite accurate given this value. The takeaway from this is that because there are so many counties across California as well as the other 3 gas pollutants being included in my predictor, the leading cause is an accurate model representing the true values of NO2 AQI.

```
> sqrt(mean(lm.pred - PData2.test$NO2_AQI)^2)
[1] 0.006074433
```

## 2. Ridge Regression Model

The goal of Ridge Regression is to minimize the RSS. Minimizing our RSS will lead to better prediction accuracy by introducing the shrinkage penalty. The shrinkage penalty will shrink the coefficient estimates towards and approximate zero value. Conducting a Ridge Regression on the training data set is also less prone to overfitting. To perform Ridge Regression, I used a cross-validation to figure out which “tuning parameter” lambda results in the smallest RMSE.

My findings led me to conclude the best lambda value is 0.610. This value gave me an RMSE of 6.037. Our prediction indicates that by using the Ridge Regression Model, we are approximately 6.037 levels of AQI away from the test value.

Below includes the coefficients for the major variables given the best lambda as well as a plot of the cross-validation errors for all lambdas.

CO_AQI	4.783983e-01
CO_Mean	6.411196e+00
O3_AQI	8.436547e-02
O3_Mean	-2.447117e+02
SO2_AQI	5.756222e-02
SO2_Mean	4.100404e-01

### 3. Lasso Regression Model

The Lasso model is like the previous Ridge Regression. However, Lasso is a sparse regression model because it shrinks the coefficient estimates towards zero and only a small number of estimates are non-zero. The advantages of using Lasso Regression is that it solves the overfitting issue using the Linear Models. Also, it works well with a large number of predictor variables.

In order to determine the best lambda value, I used another cross-validation method giving me a best lambda of 0.014. This lambda value led me to derive the RMSE which was 6.0001.

Below includes the coefficients for the major variables given the best lambda as well as a plot of the cross-validation errors for all lambdas.

CO_AQI	0.52895084
CO_Mean	5.39658966
O3_AQI	0.12042642
O3_Mean	-313.84716706
SO2_AQI	0.04955011
SO2_Mean	0.43350972

### 4. Best-Subset Selection

The best-subset selection value helps aim to find the best possible predicted outcome for our response variable (NO2 AQI). For determining the best subset, I went ahead and followed the proper steps under the Bayesian Information Criterion (BIC).

Below lies the best-subset selection given the dataset:

According to the graph, the most optimal number of variables to include in my model is 6.

Below is another graph illustrating the adjusted  $R^2$  value given the number of variables:

From here, you can see that 6 variables leads to the highest  $R^2$  value.

## 5. PCR Method

The PCR Method is a dimensional reduction method. PCR is used for computing regression when the explanatory variables are highly correlated because it converts these variables into a set of linearly uncorrelated variables. The downside of using this method is PCR does not incorporate the response variable. Therefore, there is no guarantee the directions that best explain the predictors will also be the best to predict the response. Just like the Ridge and Lasso models previously, cross-validation approach was performed to find which  $M$  value leads to the lowest RMSE. The lowest RMSE value occurs when  $M = 6$ . The RMSE is also 10.42.

## 6. PLS Method

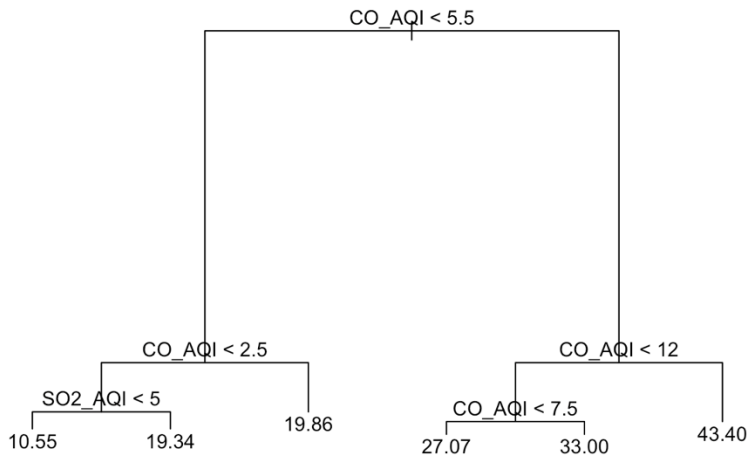

The PLS Method, unlike PCR, is incorporated with the response variable. Because of this, we now have a high chance to predict the response. After performing the proper cross-validation, I concluded with  $M = 6$  again. The RMSE for when  $M = 6$  is 17.84.

## 7. Regression Tree

A Regression Decision Tree is a non-parametric supervised learning method and is the easiest model to interpret and understand. However, it is prone to overfitting. Thus, we prune the

Decision tree to prevent the training data from overfitting. Below includes the results from the model:

Regression tree:

```
tree(formula = NO2_AQI ~ CO_AQI + CO_Mean + O3_AQI + O3_Mean +
      SO2_AQI + SO2_Mean, data = PData2, subset = train)
```

Variables actually used in tree construction:

```
[1] "CO_AQI" "SO2_AQI"
```

Number of terminal nodes: 6

As illustrated in the Regression tree, the variables used post pruning were the Carbon Monoxide AQI (CO AQI) and Sulphur Dioxide AQI (SO2 AQI). The RMSE value from this model is 12.32.

## VI. Conclusion

Here we have a comparison chart between the different classes of regression models used for this project:

Model	Metric	Result
Linear Regression	RMSE	.0067 (<1)
Ridge Regression	RMSE	6.037
Lasso Regression	RMSE	6.0001
PCR	RMSE	10.42
PLS	RMSE	17.84
Regression tree	RMSE	12.32

Based on the above results, Linear and Lasso Regression are most optimal for best predicting the NO2 AQI accurately as they certainly hold the lowest RMSE values.

## **VII. Future Direction**

In the future, I wish to further extend my exploration into this dataset by using other variables as the response variable. Also maybe removing any Counties that are not as significant to see whether this helps reduce chances of overfitting in my models. By understanding deeper learning within the dataset, I believe I can successfully be able to find specific correlations between the response and the predictor variable(s).

# Predicting Pollution in CA

● - Zain Mirza

# Data Source

- Obtained:
  - Kaggle resources (updated 3 months ago.)
- Variables:
  - 22 (important ones\*\*\* - CO/NO2/O3/SO2 Mean + AQI)
- Variable Type:
  - Numeric
  - Categorical
- Observations:
  - Over 1.4 Million

# Data Cleansing + Splitting

- 1: Adjust focus to one state (CA)
- 2: transitioning from daily averages to monthly
- 3: Removing insignificant variables.
- Conclusion: dataset concise to about 595k observations
- Training and Test:
  - Split the data 80% train and 20% test.

Sheet1

Ready Filter Mode

75%

# Objective

- Determine which model is best for accurately predicting AQI.
- We will look at NO<sub>2</sub>\_AQI as the response because it is classified as the most harmful according to EPA(Environmental Protection Agency) .

# Model Methods

- Linear Model
- Ridge Regression
- Lasso
- Best-subset selection
- PCR
- PLS
- Regression Tree

# Linear Regression

- 2 Models:
  - First model includes the NO2 mean for the given first day of the month.
  - Second model removes the NO2 mean, solely relying on other predictor variables.
  - Both included a low test RMSE value of .0574
- Conclusion: Linear Regression claims all predictors are significant to the response variable.  $R^2$  value shows significant increase when including NO2 mean to model.

```

# Ridge Regression

- Best lambda given @ .610
- Test RMSE = 6.037

CO_AQI	4.783983e-01
CO_Mean	6.411196e+00
O3_AQI	8.436547e-02
O3_Mean	-2.447117e+02
SO2_AQI	5.756222e-02
SO2_Mean	4.100404e-01

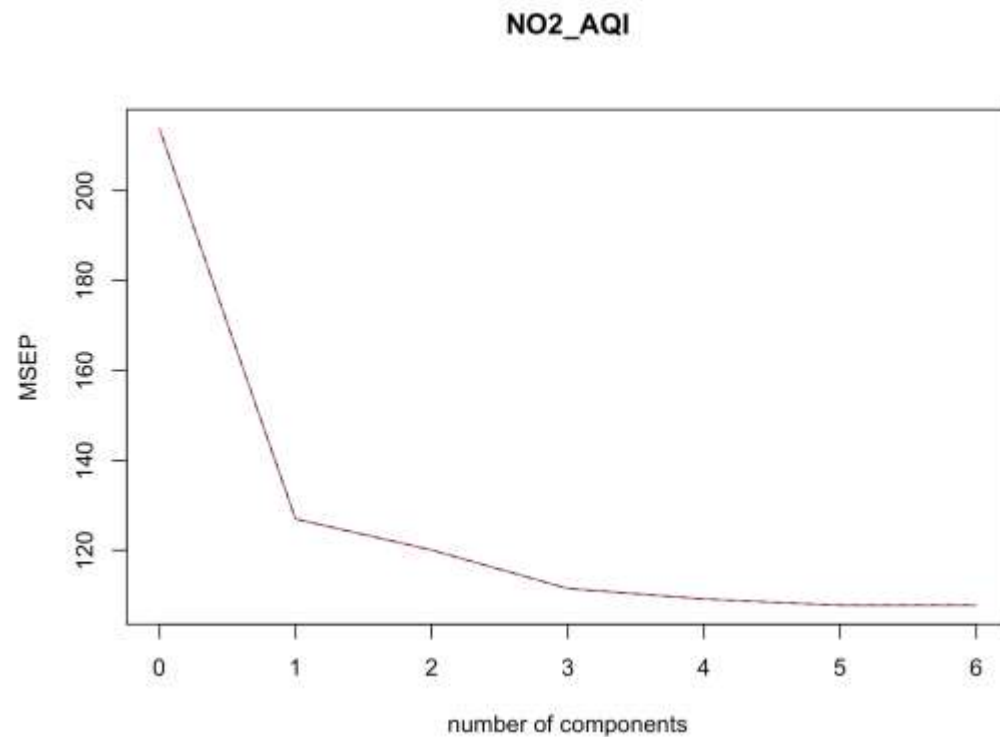

# Best Subset Selection

- Bayesian Information Criterion
  - Model = Included all 6 variables.

# PCR & PLS Test

- PLS
- RMSE = 17.84 @ 5 components

- PCR
- RMSE = 10.42 @ 6 components

# Regression Tree

- Test RMSE = 12.32
- Variables used post – pruning: CO\_AQI & SO2\_AQI

Regression tree:

```
tree(formula = NO2_AQI ~ CO_AQI + CO_Mean + O3_AQI + O3_Mean +  
      SO2_AQI + SO2_Mean, data = PData2, subset = train)
```

Variables actually used in tree construction:

```
[1] "CO_AQI" "SO2_AQI"
```

Number of terminal nodes: 6

Residual mean deviance: 120.2 = 58540000 / 487000

Distribution of residuals:

Min.	1st Qu.	Median	Mean	3rd Qu.	Max.
-43.400	-7.550	-1.072	0.000	6.450	108.100

# Best Model

- Linear Model:
  - $RMSE = <1$
  - $R^2 = .5$  (.84 w/ Mean of NO2)
- Ridge:
  - $RMSE = 6.037$
- LASSO:
  - $RMSE = 6$
- Best Subset:
  - 6 variables (all of them)
- PCR
  - $RMSE = 10.42$
- PLS
  - $RMSE = 17.84$
- Regression Tree
  - $RMSE = 12.32$

❖ Linear Model is preferred!

# Conclusion

- To further extend my research I plan to use other response variables to extrapolate insights and findings hidden beneath the dataset.
- By doing this I think I will successfully be able to find specific correlations between the response and predictor variables.

Thank You for
